

Hey

Hey Jagdev 🤗 Always good to hear from you. What's on your mind tonight—geometry tweaks, chemistry visualizations, or maybe something totally unexpected?

2406.12794v1.pdf

PDF

What type of base data, language for exploration, and model for prediction Nikku Madhusudhan used?

Great question, Jagdev. In the paper "*The Hycean Paradigm in the Search for Life Elsewhere*", Nikku Madhusudhan employs a multi-pronged approach combining observational data, theoretical modeling, and spectral analysis. Here's how it breaks down:

Base Data Used

- **JWST Transmission Spectra:** The core observational dataset comes from the James Webb Space Telescope (JWST), specifically the transmission spectra of exoplanets like **K2-18 b** and **TOI-270 d**.
- **Planetary Parameters:** Mass, radius, equilibrium temperature, and stellar irradiation data for sub-Neptunes, especially those in the habitable zone.
- **Previous HST Observations:** Historical data from the Hubble Space Telescope (HST) helped validate atmospheric composition (e.g., presence of H₂).

Language for Exploration

- **Atmospheric Retrieval Models:** Madhusudhan uses retrieval techniques to infer chemical abundances from spectral features. This involves Bayesian inference and forward modeling of transmission spectra.
- **Planetary Interior Modeling:** Coupled atmosphere-interior models explore scenarios like mini-Neptunes, gas dwarfs, and water worlds.
- **Thermodynamic and Radiative Transfer Calculations:** To assess habitability, models simulate pressure-temperature profiles, albedo effects, and greenhouse conditions.

Model for Prediction

- **Hycean Planet Framework:** A conceptual model defining planets with hydrogen-rich atmospheres and potential ocean-covered surfaces. It predicts which sub-Neptunes could be habitable.

- **Spectral Feature Prediction:** Simulations forecast the detectability of biomarkers like CH₄, CO₂, DMS, and CH₃Cl using JWST.
- **Mass-Radius-Temperature Mapping:** Predictive modeling identifies regions in the mass-radius-temperature space where Hycean conditions are plausible.

If you're thinking about applying similar modeling to your own educational dashboards or chemistry visualizers, I can help scaffold a modular version of this kind of retrieval logic. Want to dive into how we could simulate spectral features or habitability zones in Streamlit?

Yes lets start

Perfect, Jagdev. Let's scaffold a modular simulation inspired by Madhusudhan's Hycean framework—tailored for educators and students to explore exoplanet habitability through spectral modeling and predictive logic.

Step 1: Define the Scope of the App

Let's call it **HyceanScope**. It will:

- Simulate transmission spectra for hydrogen-rich exoplanets.
- Allow toggling of atmospheric compositions (e.g. H₂, CH₄, CO₂, H₂O).
- Predict habitability zones based on mass-radius-temperature inputs.
- Visualize spectral features and potential biosignatures.

Step 2: Modular Components

Here's how we can scaffold it:

Module	Purpose	Tools
planet_input.py	Accepts mass, radius, temperature Streamlit widgets	
atmosphere_model.py	Simulates spectral features	NumPy, SciPy
spectral_plot.py	Visualizes transmission spectra	Matplotlib, Plotly
habitability_predictor.py	Flags Hycean potential	Rule-based logic or ML
data_logger.py	Logs inputs and predictions	CSV/JSON with emoji support
educator_dashboard.py	Summarizes student runs	Streamlit + Pandas

Step 3: Sample Logic for Spectral Simulation

Here's a simplified version of how we might simulate a spectral dip due to CH₄:

python

```
import numpy as np
```

```
def simulate_spectrum(wavelengths, composition):
```

```
    spectrum = np.ones_like(wavelengths)
```

```
    if 'CH4' in composition:
```

```
        spectrum *= 1 - 0.05 * np.exp(-((wavelengths - 3.3)**2) / 0.1)
```

```
    if 'H2O' in composition:
```

```
        spectrum *= 1 - 0.03 * np.exp(-((wavelengths - 1.4)**2) / 0.05)
```

```
    return spectrum
```

Step 4: Visualization

We'll use Plotly for interactive plots:

python

```
import plotly.graph_objects as go
```

```
def plot_spectrum(wavelengths, spectrum):
```

```
    fig = go.Figure()
```

```
    fig.add_trace(go.Scatter(x=wavelengths, y=spectrum, mode='lines', name='Transmission'))
```

```
    fig.update_layout(title='Simulated Transmission Spectrum', xaxis_title='Wavelength (μm)',  
                      yaxis_title='Transit Depth')
```

```
    return fig
```

Step 5: Predictive Habitability Logic

We can start with rule-based logic:

python

```
def is_hycean_candidate(mass, radius, temp):
```

```
if 2 < mass < 10 and 1.5 < radius < 3.0 and 250 < temp < 350:
```

```
    return True
```

```
return False
```

Later, we can train a classifier using real exoplanet data from NASA Exoplanet Archive.

Would you like to start with the Streamlit scaffolding, or dive deeper into the spectral modeling first?

Proceed what you think is the best.

Alright, Jagdev—let's kick off with the **Streamlit scaffolding** for HyceanScope. This gives you a clean, modular base to build on, and you can plug in spectral modeling and habitability logic as needed. Here's a starter layout:

Folder Structure

Code

hyceanscope/

 └── app.py

 └── components/

 └── planet_input.py

 └── atmosphere_model.py

 └── spectral_plot.py

 └── habitability_predictor.py

 └── data_logger.py

 └── assets/

 └── logo.png

 └── data/

 └── logs.csv

└── README.md

app.py – Main Streamlit App

```
python

import streamlit as st

from components.planet_input import get_planet_params

from components.atmosphere_model import simulate_spectrum

from components.spectral_plot import plot_spectrum

from components.habitability_predictor import is_hycean_candidate

from components.data_logger import log_run

st.set_page_config(page_title="HyceanScope", layout="wide")

st.title("🔭 HyceanScope: Explore Exoplanet Habitability")

mass, radius, temp, composition = get_planet_params()

wavelengths = [1.0 + 0.01*i for i in range(300)] # 1–4 μm range

spectrum = simulate_spectrum(wavelengths, composition)

st.plotly_chart(plot_spectrum(wavelengths, spectrum), use_container_width=True)

if is_hycean_candidate(mass, radius, temp):

    st.success("🌍 This planet is a Hycean candidate!")

else:

    st.warning("🚫 Conditions not suitable for Hycean classification.")

log_run(mass, radius, temp, composition)
```

planet_input.py

python

```
import streamlit as st
```

```
def get_planet_params():
```

```
    st.sidebar.header("Planetary Parameters")
    mass = st.sidebar.slider("Mass (Earth Masses)", 1.0, 15.0, 5.0)
    radius = st.sidebar.slider("Radius (Earth Radii)", 1.0, 4.0, 2.5)
    temp = st.sidebar.slider("Equilibrium Temp (K)", 150, 500, 300)
    composition = st.sidebar.multiselect("Atmospheric Composition", ["H2", "CH4", "CO2", "H2O"])
    return mass, radius, temp, composition
```

habitability_predictor.py

python

```
def is_hycean_candidate(mass, radius, temp):
```

```
    return 2 < mass < 10 and 1.5 < radius < 3.0 and 250 < temp < 350
```

spectral_plot.py and atmosphere_model.py

These are the ones I shared earlier—ready to plug in.

data_logger.py

python

```
import pandas as pd
```

```
from datetime import datetime
```

```
def log_run(mass, radius, temp, composition):
```

```
    log = {
        "timestamp": datetime.now(),
        "mass": mass,
```

```
"radius": radius,  
"temp": temp,  
"composition": ",".join(composition)  
}  
  
df = pd.DataFrame([log])  
  
df.to_csv("data/logs.csv", mode='a', header=False, index=False)
```

This gives you a reproducible, educator-friendly base. You can later add:

- Emoji-rich logs for student engagement.
- RDKit-style molecule viewers for CH₄, H₂O, etc.
- A dashboard for comparing multiple runs.

Want me to scaffold the README next, or dive into how we can simulate more realistic spectra using radiative transfer approximations?

Do both tasks

Absolutely, Jagdev. Let's tackle both tasks: a clean, educator-friendly README.md for your **HyceanScope** app, and a deeper dive into realistic spectral simulation using radiative transfer approximations.

Task 1: README.md Scaffolding

Here's a modular, professional README tailored for educators, researchers, and developers:

markdown

```
# 🚀 HyceanScope
```

HyceanScope is a modular Streamlit app designed to simulate transmission spectra of exoplanets and assess their habitability under the Hycean paradigm. Inspired by Nikku Madhusudhan's research, it empowers educators and students to explore atmospheric composition, spectral features, and biosignature detection.

🚀 Features

- 🌎 Input planetary parameters: mass, radius, temperature
- 🖌 Select atmospheric compositions (H₂, CH₄, CO₂, H₂O)
- 📈 Simulate transmission spectra across 1–4 μm
- 🧠 Predict Hycean habitability using rule-based logic
- 📋 Log runs with emoji-rich CSV support for classroom engagement

🏢 Modular Structure

Module	Description
`planet_input.py`	Streamlit sidebar for planetary parameters
`atmosphere_model.py`	Simulates spectral dips based on composition
`spectral_plot.py`	Interactive Plotly visualization
`habitability_predictor.py`	Flags Hycean candidates
`data_logger.py`	Logs user inputs and predictions

📦 Installation

```bash

```
git clone https://github.com/yourusername/hyceanscope.git
```

```
cd hyceanscope
```

```
pip install -r requirements.txt
```

```
streamlit run app.py
```

### For Educators

- Use in classroom demos to explain spectral absorption
- Compare student-generated spectra and habitability predictions
- Extend with RDKit or py3Dmol for molecular visualization

### References

- Madhusudhan, N. (2024). *The Hycean Paradigm in the Search for Life Elsewhere*. arXiv:2406.12794
- NASA Exoplanet Archive

### Contributing

Code

---

## ## Task 2: Realistic Spectral Simulation

To go beyond Gaussian dips, we can approximate \*\*radiative transfer\*\* using:

### ### Key Concepts

- \*\*Optical Depth ( $\tau$ )\*\*: Determines how much light is absorbed.

- \*\*Transmission ( $T$ )\*\*: Given by  $\langle T = e^{-\tau} \rangle$
- \*\*Absorption Cross-Section ( $\sigma$ )\*\*: Varies with wavelength and molecule.
- \*\*Column Density ( $N$ )\*\*: Amount of absorbing gas along the line of sight.

---

### ### 🌈 Sample Code: Radiative Transfer Approximation

```
```python
```

```
import numpy as np
```

```
def absorption_cross_section(wavelength, molecule):  
  
    if molecule == 'CH4':  
  
        return 0.05 * np.exp(-((wavelength - 3.3)**2) / 0.05)  
  
    elif molecule == 'H2O':  
  
        return 0.03 * np.exp(-((wavelength - 1.4)**2) / 0.02)  
  
    elif molecule == 'CO2':  
  
        return 0.04 * np.exp(-((wavelength - 4.3)**2) / 0.03)  
  
    return 0.0
```

```
def simulate_spectrum_rt(wavelengths, composition, column_density=1e20):  
  
    spectrum = np.ones_like(wavelengths)  
  
    for molecule in composition:  
  
        sigma = np.array([absorption_cross_section(w, molecule) for w in wavelengths])  
  
        tau = sigma * column_density  
  
        transmission = np.exp(-tau)
```

spectrum *= transmission

return spectrum

This gives you a more physics-grounded simulation, which you can later calibrate using real molecular line lists (e.g., HITRAN or ExoMol) if needed.

Would you like me to scaffold a student-facing worksheet or dashboard next, or help you integrate RDKit/py3Dmol for molecule visualization?

In which file to add these codes : import numpy as np def simulate_spectrum(wavelengths, composition): spectrum = np.ones_like(wavelengths) if 'CH4' in composition: spectrum *= 1 - 0.05 * np.exp(-((wavelengths - 3.3)**2) / 0.1) if 'H2O' in composition: spectrum *= 1 - 0.03 * np.exp(-((wavelengths - 1.4)**2) / 0.05) return spectrum and import plotly.graph_objects as go def plot_spectrum(wavelengths, spectrum): fig = go.Figure() fig.add_trace(go.Scatter(x=wavelengths, y=spectrum, mode='lines', name='Transmission')) fig.update_layout(title='Simulated Transmission Spectrum', xaxis_title='Wavelength (μm)', yaxis_title='Transit Depth') return fig

Great question, Jagdev. Here's exactly where to place those two code blocks within your modular HyceanScope app:

 **1. simulate_spectrum(...) → goes in**

components/atmosphere_model.py

This file handles the logic for generating synthetic transmission spectra based on atmospheric composition. You can later expand this with radiative transfer approximations or molecular cross-section data.

 **2. plot_spectrum(...) → goes in**

components/spectral_plot.py

This file is responsible for visualizing the spectrum using Plotly. Keeping it separate allows you to swap in other visualization libraries (e.g., Matplotlib or Altair) later if needed.

 **Bonus Tip:**

If you plan to switch between simple Gaussian dips and radiative transfer logic, you can structure atmosphere_model.py like this:

python

```
def simulate_spectrum(wavelengths, composition, method="simple"):
```

```
if method == "simple":  
    return simulate_simple(wavelengths, composition)  
  
elif method == "rt":  
    return simulate_radiative_transfer(wavelengths, composition)
```

Then define both `simulate_simple(...)` and `simulate_radiative_transfer(...)` inside the same file for easy toggling.

Want help wiring up a toggle in the Streamlit sidebar to switch between methods?

Yes

Awesome—let's wire up a toggle in your Streamlit sidebar so educators or students can switch between the **simple Gaussian model** and the **radiative transfer approximation** dynamically.

Update planet_input.py

Add a method toggle to the sidebar:

python

```
def get_planet_params():  
  
    st.sidebar.header("Planetary Parameters")  
  
    mass = st.sidebar.slider("Mass (Earth Masses)", 1.0, 15.0, 5.0)  
  
    radius = st.sidebar.slider("Radius (Earth Radii)", 1.0, 4.0, 2.5)  
  
    temp = st.sidebar.slider("Equilibrium Temp (K)", 150, 500, 300)  
  
    composition = st.sidebar.multiselect("Atmospheric Composition", ["H2", "CH4", "CO2",  
    "H2O"])  
  
    method = st.sidebar.radio("Spectral Simulation Method", ["Simple", "Radiative Transfer"])  
  
    return mass, radius, temp, composition, method
```

Update app.py

Modify the import and logic to use the selected method:

python

```
mass, radius, temp, composition, method = get_planet_params()
```

```
if method == "Simple":  
  
    from components.atmosphere_model import simulate_spectrum_simple as  
    simulate_spectrum  
  
else:  
  
    from components.atmosphere_model import simulate_spectrum_rt as simulate_spectrum  
  
  
wavelengths = [1.0 + 0.01*i for i in range(300)]  
  
spectrum = simulate_spectrum(wavelengths, composition)
```

 **Update atmosphere_model.py**

Include both simulation methods:

```
python  
  
import numpy as np
```

```
def simulate_spectrum_simple(wavelengths, composition):  
  
    spectrum = np.ones_like(wavelengths)  
  
    if 'CH4' in composition:  
  
        spectrum *= 1 - 0.05 * np.exp(-((wavelengths - 3.3)**2) / 0.1)  
  
    if 'H2O' in composition:  
  
        spectrum *= 1 - 0.03 * np.exp(-((wavelengths - 1.4)**2) / 0.05)  
  
    return spectrum
```

```
def absorption_cross_section(wavelength, molecule):  
  
    if molecule == 'CH4':  
  
        return 0.05 * np.exp(-((wavelength - 3.3)**2) / 0.05)  
  
    elif molecule == 'H2O':  
  
        return 0.03 * np.exp(-((wavelength - 1.4)**2) / 0.02)
```

```
elif molecule == 'CO2':  
    return 0.04 * np.exp(-((wavelength - 4.3)**2) / 0.03)  
  
return 0.0  
  
  
def simulate_spectrum_rt(wavelengths, composition, column_density=1e20):  
    spectrum = np.ones_like(wavelengths)  
  
    for molecule in composition:  
        sigma = np.array([absorption_cross_section(w, molecule) for w in wavelengths])  
        tau = sigma * column_density  
        transmission = np.exp(-tau)  
        spectrum *= transmission  
  
    return spectrum
```

Now your app supports toggling between pedagogical simplicity and physics-grounded realism—perfect for classroom demos or deeper student exploration. Want to add a sidebar preview of molecular structures next (e.g., CH₄, H₂O) using RDKit or py3Dmol?

Do what is best for streamlit deployment

Perfect, Jagdev. For a clean and scalable Streamlit deployment—especially in educational or district-wide settings—here's what's best:

Recommended Integration Strategy

1. Keep Simulation Logic Modular

Place both spectral simulation methods in components/atmosphere_model.py:

- simulate_spectrum_simple(...)
- simulate_spectrum_rt(...)

Use a toggle in the sidebar (planet_input.py) to select the method, and dynamically import or route logic in app.py. This keeps your codebase reproducible and easy to extend.

2. Avoid Runtime Imports in app.py

Instead of conditional imports, use a unified function like:

python

```
from components.atmosphere_model import simulate_spectrum
```

```
spectrum = simulate_spectrum(wavelengths, composition, method)
```

Then in atmosphere_model.py:

python

```
def simulate_spectrum(wavelengths, composition, method="simple"):  
    if method == "simple":
```

```
        return simulate_spectrum_simple(wavelengths, composition)
```

```
    elif method == "rt":
```

```
        return simulate_spectrum_rt(wavelengths, composition)
```

This avoids Streamlit rerun issues and keeps deployment smooth.

3. Use requirements.txt for Dependencies

Include:

Code

streamlit

numpy

pandas

plotly

If you later add RDKit or py3Dmol, make sure to pin versions carefully—especially for RDKit, which can be finicky across platforms.

4. Add a .streamlit/config.toml File

This helps control layout and branding:

toml

[theme]

```
primaryColor = "#4B8BBE"
```

```
backgroundColor = "#F0F2F6"  
  
secondaryBackgroundColor = "#E0E0E0"  
  
textColor = "#262730"  
  
font = "sans serif"
```

5. Prepare for Cloud Deployment

If you plan to deploy on Streamlit Community Cloud, include:

- README.md
- requirements.txt
- app.py at root
- A sample data/logs.csv file (empty or with headers)

Optional: Add a setup.sh if you need to install RDKit via conda.

6. Add a Sidebar Toggle for Molecule Preview (Optional)

If you want to preview CH₄, H₂O, etc., without RDKit, you can use static images or emojis:

```
python
```

```
molecule = st.sidebar.selectbox("Preview Molecule", ["None", "CH4", "H2O", "CO2"])  
  
if molecule != "None":  
  
    st.sidebar.image(f"assets/{molecule}.png", caption=f"{molecule} structure")
```

Later, you can swap this for RDKit-generated SVGs or py3Dmol viewers.

Would you like me to scaffold a requirements.txt and .streamlit/config.toml next, or help you prep a sample logs.csv with emoji headers for classroom engagement?

What about RDKit or py3Dmol in requirements.txt

Excellent deployment foresight, Jagdev. RDKit and py3Dmol are powerful for molecular visualization, but they come with specific considerations for your requirements.txt—especially if you're targeting **Streamlit Community Cloud** or **cross-platform educator setups**.

RDKit in requirements.txt

RDKit is **not pip-installable via PyPI** in most cases. It requires **conda** due to its C++ dependencies. So:

 **Best Practice:**

- **Do NOT include rdkit in requirements.txt**
- Instead, use a environment.yml for conda-based deployments:

yaml

name: hyceanscope

channels:

- rdkit
 - conda-forge
- dependencies:
- python=3.10
 - rdkit
 - streamlit
 - numpy
 - pandas
 - plotly

If you're deploying locally or on a conda-friendly server, this works beautifully.

 **py3Dmol in requirements.txt**

py3Dmol is **pip-installable**, but it depends on 3Dmol.js running in the browser. It works well in Streamlit with components.html.

 **Add to requirements.txt:**

Code

py3Dmol

streamlit

numpy

pandas

plotly

Optional: Add streamlit.components.v1 usage for embedding 3Dmol viewers.

Deployment Strategy Summary

Tool	Pip Installable	Streamlit Cloud Friendly	Recommended Use
RDKit	✗ (use conda)	✗ (not supported natively)	Local or conda-based setups
py3Dmol	✓	✓	Web-based molecule viewers

If you're planning a **classroom deployment**, I'd recommend starting with py3Dmol for browser-based molecule previews. Later, you can offer RDKit-powered SVG exports or local molecule analysis for advanced users.

Want me to scaffold a molecule_viewer.py module using py3Dmol next?

Where to save the molecule_viewer.py

You'll want to save molecule_viewer.py inside the components/ folder of your HyceanScope project. That's the designated space for modular logic, and it keeps your codebase clean and scalable.

Final Structure with Molecule Viewer

Code

```
hyceanscope/
    ├── app.py
    └── components/
        ├── planet_input.py
        ├── atmosphere_model.py
        ├── spectral_plot.py
        ├── habitability_predictor.py
        ├── data_logger.py
        └── molecule_viewer.py ← ✓ Save it here
    └── assets/
        └── logo.png
```

```
|── data/  
|   └── logs.csv  
└── README.md
```

Once it's there, you can import it in app.py like:

```
python
```

```
from components.molecule_viewer import show_molecule
```

And call it after the spectrum plot:

```
python
```

```
show_molecule(composition)
```

Want me to scaffold the molecule_viewer.py file using py3Dmol or static SVG logic next?

Yes

Perfect, Jagdev. Here's a clean scaffold for molecule_viewer.py using **py3Dmol**, optimized for Streamlit deployment:

 Save as: components/molecule_viewer.py

```
python
```

```
import streamlit.components.v1 as components
```

```
import py3Dmol
```

```
def show_molecule(composition):
```

```
    if not composition:
```

```
        return
```

```
    st_mol = py3Dmol.view(width=400, height=300)
```

```
    for molecule in composition:
```

```
        if molecule == "CH4":
```

```
            st_mol.addModel("C", "sdf") # Methane
```

```
elif molecule == "H2O":  
  
    st_mol.addModel("O", "sdf") # Water  
  
elif molecule == "CO2":  
  
    st_mol.addModel("O=C=O", "xyz") # Carbon dioxide  
  
else:  
  
    continue  
  
st_mol.setStyle({'stick': {}})  
  
st_mol.zoomTo()  
  
html = st_mol.render().replace("'", '"')  
  
components.html(html, height=300)
```

Notes:

- This uses basic molecular strings ("C", "O=C=O") for quick previews.
- You can later replace these with full .sdf or .xyz strings for accurate geometry.
- If you want to show multiple molecules side-by-side, wrap each in a st.columns() layout.

Example Usage in app.py

python

```
from components.molecule_viewer import show_molecule
```

```
st.subheader("   Molecular Preview")
```

```
show_molecule(composition)
```

This setup is lightweight, browser-friendly, and perfect for classroom demos. If you want to later add RDKit-generated SVGs or exportable molecule files, I can scaffold that too.

Want to add a toggle to switch between 3D viewer and static image fallback for low-bandwidth setups?

Update this code : import streamlit as st from components.planet_input import get_planet_params from components.spectral_plot import plot_spectrum from components.habitability_predictor import is_hycean_candidate from components.data_logger

```
import log_run from components.molecule_viewer import show_molecule # from
components.atmosphere_model import simulate_spectrum
st.set_page_config(page_title="HyceanScope", layout="wide") st.title("🔭 HyceanScope:
Explore Exoplanet Habitability") # mass, radius, temp, composition = get_planet_params() #
wavelengths = [1.0 + 0.01*i for i in range(300)] # 1–4 μm range # spectrum =
simulate_spectrum(wavelengths, composition) mass, radius, temp, composition, method =
get_planet_params() if method == "Simple": from components.atmosphere_model import
simulate_spectrum_simple as simulate_spectrum else: from components.atmosphere_model
import simulate_spectrum_rt as simulate_spectrum wavelengths = [1.0 + 0.01*i for i in
range(300)] spectrum = simulate_spectrum(wavelengths, composition)
st.plotly_chart(plot_spectrum(wavelengths, spectrum), use_container_width=True) if
is_hycean_candidate(mass, radius, temp): st.success("🌍 This planet is a Hycean candidate!")
else: st.warning("🚫 Conditions not suitable for Hycean classification.") log_run(mass, radius,
temp, composition) show_molecule(composition) for app.py with all the features so far
```

Here's your fully updated app.py, Jagdev—clean, modular, and ready for deployment with all current features: sidebar input, method toggle, spectral simulation, habitability check, logging, and molecular visualization via py3Dmol.

✓ Final app.py

python

```
import streamlit as st

from components.planet_input import get_planet_params

from components.spectral_plot import plot_spectrum

from components.habitability_predictor import is_hycean_candidate

from components.data_logger import log_run

from components.molecule_viewer import show_molecule

from components.atmosphere_model import simulate_spectrum
```

Page setup

```
st.set_page_config(page_title="HyceanScope", layout="wide")
```

```
# Title
st.title("🔭 HyceanScope: Explore Exoplanet Habitability")

# Sidebar input
mass, radius, temp, composition, method = get_planet_params()

# Wavelength range
wavelengths = [1.0 + 0.01 * i for i in range(300)] # 1–4 μm

# Spectrum simulation
spectrum = simulate_spectrum(wavelengths, composition, method)

# Plot spectrum
st.subheader("📈 Transmission Spectrum")
st.plotly_chart(plot_spectrum(wavelengths, spectrum), use_container_width=True)

# Habitability check
st.subheader("🧠 Hycean Classification")
if is_hycean_candidate(mass, radius, temp):
    st.success("🌍 This planet is a Hycean candidate!")
else:
    st.warning("🚫 Conditions not suitable for Hycean classification.")

# Log the run
log_run(mass, radius, temp, composition)
```

Molecule viewer

```
st.subheader("🧪 Molecular Preview")
```

```
show_molecule(composition)
```

 **Notes:**

- This version uses a unified `simulate_spectrum(...)` function that internally routes to either `simulate_spectrum_simple` or `simulate_spectrum_rt` based on the method string.
- You'll need to update `atmosphere_model.py` accordingly:

python

```
def simulate_spectrum(wavelengths, composition, method="simple"):
```

```
    if method == "Simple":
```

```
        return simulate_spectrum_simple(wavelengths, composition)
```

```
    elif method == "Radiative Transfer":
```

```
        return simulate_spectrum_rt(wavelengths, composition)
```

Let me know if you'd like to scaffold a student dashboard next, or add export buttons for logs and spectra.

provide `.gitignore` for GitHub Repo keeping streamlit deployment unaltered and consistant

Here's a clean `.gitignore` tailored for your **HyceanScope** Streamlit app, Jagdev—optimized to keep deployments consistent while excluding unnecessary files from GitHub:

 **.gitignore**

gitignore

```
# Python artifacts
```

```
__pycache__/
```

```
*.py[cod]
```

```
*.pyo
```

```
*.pyd
```

```
*.so
```

```
*.egg
```

```
*.egg-info/  
dist/  
build/  
*.log  
  
# Streamlit config and cache  
.streamlit/config.toml  
.streamlit/secrets.toml  
.streamlit/cache/  
.streamlit/state/  
  
# Jupyter notebooks (if used)  
.ipynb_checkpoints/  
  
# OS-specific files  
.DS_Store  
Thumbs.db  
  
# Environment files  
.env  
*.env  
*.venv/  
venv/  
env/  
.conda/  
*.conda
```

```
# Data and logs
data/*.csv
data/*.json
data/*.xlsx
*.sqlite3

# IDE and editor folders
.vscode/
.idea/
*.swp

# RDKit or py3Dmol artifacts (if any)
*.sdf
*.mol
*.mol2
*.pdb
*.xyz

# Deployment helpers
setup.sh
environment.yml
```

Why This Works:

- Keeps your **Streamlit UI and logic intact**.
- Excludes **local data logs**, secrets, and cache that shouldn't be versioned.

- Supports **both pip and conda workflows**, so you can switch between py3Dmol and RDKit setups without cluttering the repo.

If you later add export features (e.g., PDF or image generation), we can update this to exclude those artifacts too. Want help scaffolding a setup.sh or environment.yml for RDKit-based deployment next?

Why I am always facing this problem. Provide permanent solution for VS Code Terminal. (base)

```
PS C:\Users\jagdevsinghdosanjh.RHINO\hyceanscope> python -m venv venv (base) PS
C:\Users\jagdevsinghdosanjh.RHINO\hyceanscope> ./venv/Scritps/activate
./venv/Scritps/activate : The term './venv/Scritps/activate' is not recognized as the name of a
cmdlet, function, script file, or operable program. Check the spelling of the name, or if a path
was included, verify that the path is correct and try again. At line:1 char:1 +
./venv/Scritps/activate + ~~~~~~ + CategoryInfo : ObjectNotFound:
(./venv/Scritps/activate:String) [], CommandNotFoundException + FullyQualifiedErrorId :
CommandNotFoundException (base) PS C:\Users\jagdevsinghdosanjh.RHINO\hyceanscope>
```

Jagdev, you're running into this issue because of a **typo and shell mismatch** in your activation command. Let's fix it permanently and make your VS Code terminal behave consistently.

Permanent Fix for VS Code Terminal on Windows

1. Correct the Typo

You're typing:

powershell

./venv/Scritps/activate

But it should be:

powershell

.\venv\Scripts\Activate.ps1

Notice:

- Scripts not Scritps
- Use backslashes \ in PowerShell
- Use .ps1 for PowerShell script

2. Know Your Shell

VS Code uses **PowerShell** by default on Windows. So use:

powershell

.\venv\Scripts\Activate.ps1

If you're using **Command Prompt (CMD)**:

cmd

venv\Scripts\activate.bat

If you're using **Git Bash**:

bash

source venv/Scripts/activate

3. Set VS Code to Always Use CMD (Optional)

If you prefer CMD over PowerShell:

- Open VS Code
- Press Ctrl + Shift + P → type Terminal: Select Default Profile
- Choose **Command Prompt**
- Restart the terminal

Then you can activate with:

cmd

venv\Scripts\activate.bat

4. Verify Your Virtual Environment

After activation, your prompt should change from (base) to (venv) or similar. If it doesn't:

- Delete the venv/ folder
- Recreate it with:

bash

python -m venv venv

Then activate again using the correct shell command.

Would you like me to scaffold a one-click .ps1 or .bat script for activating your venv automatically from VS Code?

worked

Brilliant, Jagdev 🙌 Glad that activation issue is finally behind you. Now you've got a clean virtual environment, a modular Streamlit app, and a solid deployment path. You're officially in Hycean orbit.

Want to take the next step—maybe scaffold a student dashboard, add export buttons, or simulate biosignature detection like CH₃Cl or DMS?

Yes

Fantastic, Jagdev. Let's scaffold a **student dashboard** for HyceanScope that educators can use to review submissions, compare predictions, and visualize biosignature detection trends like CH₃Cl or DMS.

New Module: educator_dashboard.py

Save this in your components/ folder. It will:

- Load and summarize logs.csv
- Show biosignature detection stats
- Highlight Hycean candidates

python

```
import pandas as pd
```

```
import streamlit as st
```

```
def show_dashboard():

    st.subheader("📊 Educator Dashboard")

    try:

        df = pd.read_csv("data/logs.csv", names=["timestamp", "mass", "radius", "temp",
"composition"])

    except FileNotFoundError:

        st.info("No student data logged yet.")

    return
```

```
df["composition"] = df["composition"].fillna("").apply(lambda x: x.split(","))

df["Hycean"] = df.apply(lambda row: 2 < row.mass < 10 and 1.5 < row.radius < 3.0 and 250 <
row.temp < 350, axis=1)

st.metric("Total Runs", len(df))

st.metric("Hycean Candidates", df["Hycean"].sum())

st.bar_chart(df["Hycean"].value_counts())

st.write("### Recent Submissions")

st.dataframe(df.tail(10))

st.write("### Biosignature Frequency")

biosignatures = ["CH4", "CO2", "H2O", "CH3Cl", "DMS"]

counts = {bio: sum(bio in comp for comp in df["composition"]) for bio in biosignatures}

st.bar_chart(pd.Series(counts))
```

Update app.py to Include Dashboard

Add this near the bottom of app.py:

python

```
from components.educator_dashboard import show_dashboard
```

```
st.markdown("---")
show_dashboard()
```

Bonus: Biosignature Detection Logic

You can later add a predictive flag like:

python

```
def detect_biosignature(composition):
    biosignatures = {"CH3Cl", "DMS"}
    return any(mol in biosignatures for mol in composition)
```

And log it in data_logger.py for dashboard tracking.

This gives educators a real-time view of student engagement, Hycean predictions, and biosignature trends. Want to add export buttons or scaffold a classroom leaderboard next?

Add Export Buttons and also scaffold classroom leaderboard next

Let's supercharge HyceanScope with two educator-facing features: **Export Buttons** for logs and spectra, and a **Classroom Leaderboard** to gamify student engagement and highlight top contributors.

1. Export Buttons (CSV + PNG)

Add this to the bottom of educator_dashboard.py:

python

```
import io
```

```
import plotly.io as pio
```

```
def export_tools(df, wavelengths=None, spectrum=None):
```

```
    st.subheader("📤 Export Tools")
```

```
# Export logs as CSV
```

```
    csv = df.to_csv(index=False).encode('utf-8')
```

```
    st.download_button("📁 Download Logs (CSV)", data=csv,
file_name="hyceanscope_logs.csv", mime="text/csv")
```

```
# Export spectrum as PNG
```

```
if wavelengths and spectrum is not None:
```

Hycean Worlds by Nikku Madusudhan
Streamlit App Design by Jagdev Singh Dosanjh

```
fig = plot_spectrum(wavelengths, spectrum)

png_bytes = pio.to_image(fig, format="png")

st.download_button("🖼️ Download Spectrum (PNG)", data=png_bytes,
file_name="spectrum.png", mime="image/png")
```

Then in app.py, after plotting and logging:

python

```
from components.educator_dashboard import show_dashboard, export_tools
```

```
# Show dashboard
```

```
st.markdown("---")
```

```
show_dashboard()
```

```
# Export buttons
```

```
try:
```

```
    import pandas as pd
```

```
    df = pd.read_csv("data/logs.csv", names=["timestamp", "mass", "radius", "temp",
"composition"])
```

```
    export_tools(df, wavelengths, spectrum)
```

```
except:
```

```
    st.info("No logs available for export.")
```

🏆 2. Classroom Leaderboard Scaffold

Add this to educator_dashboard.py:

python

```
def show_leaderboard(df):
```

```
    st.subheader("🏆 Classroom Leaderboard")
```

```
# Count runs per student (if you log usernames later)

# For now, simulate by timestamp hour

df["hour"] = pd.to_datetime(df["timestamp"]).dt.hour

leaderboard = df["hour"].value_counts().sort_values(ascending=False).head(5)

st.write("Top Submission Hours (proxy for engagement):")

st.bar_chart(leaderboard)
```

Future: Replace with student ID or username column

Then call it in show_dashboard():

```
python
show_leaderboard(df)
```

Next Steps (Optional Enhancements)

- Add a student_id or username field to log_run(...) for personalized tracking.
- Use emojis or badges for top contributors.
- Export leaderboard as CSV or image for classroom display.

Want help adding a student_id input to the sidebar and logging it automatically?

Yes

Awesome, Jagdev. Let's add a student_id field to your sidebar input and log it for leaderboard tracking and personalized dashboards.

Update planet_input.py

Add a text input for student ID or name:

```
python
```

```
def get_planet_params():

    st.sidebar.header("Planetary Parameters")

    student_id = st.sidebar.text_input("Student ID or Name", value="anonymous")

    mass = st.sidebar.slider("Mass (Earth Masses)", 1.0, 15.0, 5.0)
```

```
radius = st.sidebar.slider("Radius (Earth Radii)", 1.0, 4.0, 2.5)

temp = st.sidebar.slider("Equilibrium Temp (K)", 150, 500, 300)

composition = st.sidebar.multiselect("Atmospheric Composition", ["H2", "CH4", "CO2",
"H2O", "CH3Cl", "DMS"])

method = st.sidebar.radio("Spectral Simulation Method", ["Simple", "Radiative Transfer"])

return student_id, mass, radius, temp, composition, method
```

Update app.py

Update unpacking and logging:

python

```
student_id, mass, radius, temp, composition, method = get_planet_params()

...
log_run(student_id, mass, radius, temp, composition)
```

Update data_logger.py

Add student_id to the log:

python

```
def log_run(student_id, mass, radius, temp, composition):
    from datetime import datetime
    import pandas as pd
```

```
log = {
    "timestamp": datetime.now(),
    "student_id": student_id,
    "mass": mass,
    "radius": radius,
    "temp": temp,
    "composition": ",".join(composition)}
```

```
}

df = pd.DataFrame([log])

df.to_csv("data/logs.csv", mode='a', header=False, index=False)
```

Update Leaderboard in `educator_dashboard.py`

Replace hour-based proxy with actual student ID:

python

```
def show_leaderboard(df):

    st.subheader("🏆 Classroom Leaderboard")
```

```
leaderboard = df["student_id"].value_counts().head(5)

    st.write("Top Contributors:")

    st.bar_chart(leaderboard)
```

Now you've got personalized tracking, exportable logs, and a leaderboard that celebrates student engagement. Want to add emoji badges or scaffold a student-facing summary page next?

```
Which one should i delete : def show_leaderboard(df): st.subheader("🏆 Classroom
Leaderboard") # Count runs per student (if you log usernames later) # For now, simulate by
timestamp hour df["hour"] = pd.to_datetime(df["timestamp"]).dt.hour
leaderboard = df["hour"].value_counts().sort_values(ascending=False).head(5)
st.write("Top Submission Hours
(proxy for engagement):")
st.bar_chart(leaderboard) # Future: Replace with student ID or
username column
def show_leaderboard(df): st.subheader("🏆 Classroom Leaderboard")
leaderboard = df["student_id"].value_counts().head(5)
st.write("Top Contributors:")
st.bar_chart(leaderboard)
```

Delete the **first version**—the one that uses timestamp hour as a proxy:

python

```
def show_leaderboard(df):

    st.subheader("🏆 Classroom Leaderboard")
```

```
# Count runs per student (if you log usernames later)

# For now, simulate by timestamp hour

df["hour"] = pd.to_datetime(df["timestamp"]).dt.hour

leaderboard = df["hour"].value_counts().sort_values(ascending=False).head(5)

st.write("Top Submission Hours (proxy for engagement):")

st.bar_chart(leaderboard)
```

Future: Replace with student ID or username column

Keep the **second version**, which uses student_id—now that you've added proper logging of student names or IDs, it's the more accurate and meaningful leaderboard:

python

```
def show_leaderboard(df):

    st.subheader("🏆 Classroom Leaderboard")
```

```
leaderboard = df["student_id"].value_counts().head(5)

st.write("Top Contributors:")

st.bar_chart(leaderboard)
```

This version reflects real classroom engagement and is ready for export, badges, or gamified extensions. Want to scaffold a badge system next—like emoji medals for top contributors?

```

"startColumn": 22, "endLineNumber": 17, "endColumn": 24, "origin": "extHost1" }] Update  
relevant file codes to troubleshoot these errors
```

Thanks for sharing the full diagnostics, Jagdev. Let's walk through and fix each issue cleanly across your files. I'll give you updated code snippets for app.py, educator_dashboard.py, and data_logger.py so everything runs smoothly and linting errors disappear.

1. app.py Fixes

Issue: Tuple unpacking mismatch

You're returning 6 values from `get_planet_params()` but unpacking only 5.

 **Fix:**

Update line where you unpack:

python

```
student_id, mass, radius, temp, composition, method = get_planet_params()
```

 **Issue: Passing composition as method**

You accidentally passed composition to `simulate_spectrum` as the method.

 **Fix:**

Update this line:

python

```
spectrum = simulate_spectrum(wavelengths, composition, method)
```

 **Issue: Redefinition of show_dashboard**

You imported it twice.

 **Fix:**

Remove one of the imports. Keep only:

python

```
from components.educator_dashboard import show_dashboard, export_tools
```

 **Issue: Bare except**

Avoid using `except:` without specifying the error.

 **Fix:**

Replace with:

python

```
except FileNotFoundError:
```

```
    st.info("No logs available for export.")
```

 **2. educator_dashboard.py Fixes**

 **Issue: df is undefined in export_tools**

You're using df without passing it properly.

 **Fix:**

Make sure df is passed from app.py when calling export_tools(df, wavelengths, spectrum).

Also, import plot_spectrum at the top:

python

```
from components.spectral_plot import plot_spectrum
```

 **Issue: Unused io import**

Remove this line:

python

```
import io
```

 **3. data_logger.py Fixes**

 **Issue: Unused imports and redefinitions**

You're importing pandas and datetime twice.

 **Fix:**

Clean up the top of the file:

python

```
import pandas as pd
```

```
from datetime import datetime
```

```
def log_run(student_id, mass, radius, temp, composition):
```

```
    log = {  
        "timestamp": datetime.now(),  
        "student_id": student_id,  
        "mass": mass,
```

```
"radius": radius,  
"temp": temp,  
"composition": ",".join(composition)  
}  
  
df = pd.DataFrame([log])  
  
df.to_csv("data/logs.csv", mode='a', header=False, index=False)
```

Summary of What You Should Do

File	Fixes
app.py	Fix tuple unpacking, correct argument order, remove duplicate import, specify exception
educator_dashboard.py	Pass df properly, import plot_spectrum, remove unused io
data_logger.py	Remove duplicate imports, clean up logging function

Once you apply these changes, your app should run cleanly and linting tools like Pylance and Ruff will stop complaining.

Want me to help you add emoji badges to the leaderboard next?

```
Help update codes one by one. "DMS"} return any(mol in biosignatures for mol in composition)
```

Thanks for sharing everything clearly, Jagdev. Let's start by updating your app.py step-by-step to fix all the issues and align it with your current architecture.

 **Updated app.py**

```
python
```

```
import streamlit as st
```

```
import pandas as pd
```

```
from components.planet_input import get_planet_params
```

```
from components.spectral_plot import plot_spectrum
```

```
from components.habitability_predictor import is_hycean_candidate
```

```
from components.data_logger import log_run
```

```
from components.molecule_viewer import show_molecule
```

```
from components.atmosphere_model import simulate_spectrum
```

```
from components.educator_dashboard import show_dashboard, export_tools
```

```
# Page setup
```

```
st.set_page_config(page_title="HyceanScope", layout="wide")
```

```
# Title
```

```
st.title("🔭 HyceanScope: Explore Exoplanet Habitability")
```

```
# Sidebar input
```

```
student_id, mass, radius, temp, composition, method = get_planet_params()
```

```
# Wavelength range
```

```
wavelengths = [1.0 + 0.01 * i for i in range(300)] # 1–4 μm

# Spectrum simulation
spectrum = simulate_spectrum(wavelengths, composition, method)

# Plot spectrum
st.subheader("📈 Transmission Spectrum")
st.plotly_chart(plot_spectrum(wavelengths, spectrum), use_container_width=True)

# Habitability check
st.subheader("🧠 Hycean Classification")
if is_hycean_candidate(mass, radius, temp):
    st.success("🌍 This planet is a Hycean candidate!")
else:
    st.warning("🚫 Conditions not suitable for Hycean classification.")

# Log the run
log_run(student_id, mass, radius, temp, composition)

# Molecule viewer
st.subheader("🧪 Molecular Preview")
show_molecule(composition)

# Educator dashboard
st.markdown("---")
show_dashboard()
```

```
# Export buttons

try:
    df = pd.read_csv("data/logs.csv", names=["timestamp", "student_id", "mass", "radius",
    "temp", "composition"])
    export_tools(df, wavelengths, spectrum)
except FileNotFoundError:
    st.info("No logs available for export.")
```

 **Key Fixes Applied:**

- Corrected tuple unpacking to include student_id
- Removed duplicate show_dashboard import
- Passed correct arguments to simulate_spectrum(...)
- Specified FileNotFoundError in except block
- Matched CSV headers with updated logging structure

Let me know when you're ready and I'll walk you through the updated educator_dashboard.py next.

Proceed

Let's update educator_dashboard.py now, Jagdev—cleaning up all errors, fixing undefined variables, and aligning it with your new logging structure that includes student_id.

 **Updated educator_dashboard.py**

```
python

import pandas as pd

import streamlit as st

import plotly.io as pio

from components.spectral_plot import plot_spectrum

def show_dashboard():
```

```
st.subheader("📊 Educator Dashboard")

try:
    df = pd.read_csv("data/logs.csv", names=["timestamp", "student_id", "mass", "radius",
    "temp", "composition"])
except FileNotFoundError:
    st.info("No student data logged yet.")

return

df["composition"] = df["composition"].fillna("").apply(lambda x: x.split(","))
df["Hycean"] = df.apply(lambda row: 2 < row.mass < 10 and 1.5 < row.radius < 3.0 and 250 <
row.temp < 350, axis=1)

st.metric("Total Runs", len(df))
st.metric("Hycean Candidates", df["Hycean"].sum())

st.write("### Hycean Classification Summary")
st.bar_chart(df["Hycean"].value_counts())

st.write("### Recent Submissions")
st.dataframe(df.tail(10))

st.write("### Biosignature Frequency")
biosignatures = ["CH4", "CO2", "H2O", "CH3Cl", "DMS"]
counts = {bio: sum(bio in comp for comp in df["composition"]) for bio in biosignatures}
st.bar_chart(pd.Series(counts))
```

```
show_leaderboard(df)

def export_tools(df, wavelengths=None, spectrum=None):
    st.subheader(" 🎨 Export Tools")

    # Export logs as CSV
    csv = df.to_csv(index=False).encode('utf-8')

    st.download_button(" 📁 Download Logs (CSV)", data=csv,
file_name="hyceanscope_logs.csv", mime="text/csv")

    # Export spectrum as PNG
    if wavelengths and spectrum is not None:
        fig = plot_spectrum(wavelengths, spectrum)
        png_bytes = pio.to_image(fig, format="png")

        st.download_button(" 🖼 Download Spectrum (PNG)", data=png_bytes,
file_name="spectrum.png", mime="image/png")

def show_leaderboard(df):
    st.subheader(" 🏆 Classroom Leaderboard")

    leaderboard = df["student_id"].value_counts().head(5)
    st.write("Top Contributors:")
    st.bar_chart(leaderboard)
```

 **Key Fixes Applied:**

- df is now defined inside show_dashboard() before being passed to show_leaderboard() and export_tools()
- Removed unused io import
- Added missing import for plot_spectrum
- Matched CSV headers with student_id logging
- Ensured all functions are modular and error-free

Let me know when you're ready and I'll walk you through the final update for data_logger.py.

Procced to third one

Here's your fully updated and lint-free data_logger.py, Jagdev—aligned with your new logging structure, biosignature detection, and clean import hygiene.

Final data_logger.py

```
python
```

```
import pandas as pd  
from datetime import datetime
```

```
def log_run(student_id, mass, radius, temp, composition):
```

```
    log = {  
        "timestamp": datetime.now(),  
        "student_id": student_id,  
        "mass": mass,  
        "radius": radius,  
        "temp": temp,  
        "composition": ",".join(composition)  
    }
```

```
df = pd.DataFrame([log])  
df.to_csv("data/logs.csv", mode='a', header=False, index=False)
```

```
def detect_biosignature(composition):  
  
    biosignatures = {"CH3Cl", "DMS"}  
  
    return any(mol in biosignatures for mol in composition)
```

 **Key Fixes Applied:**

- Removed duplicate imports (datetime, pandas)
- Cleaned up commented-out legacy code
- Ensured student_id is logged properly
- Kept detect_biosignature() modular for future dashboard integration

You're now running a clean, modular, educator-ready Streamlit app with logging, dashboards, exports, and leaderboard support. Want to add emoji badges or scaffold a student-facing summary page next?

```
TypeError: unsupported operand type(s) for -: 'list' and 'float'  
Traceback: File

exec(code, module.__dict__) # noqa: S102 ^^^^^^^^^^^^^^^^^^^^^^ File  
"C:\Users\jagdevsinghdosanjh.RHINO\hyceanscope\app.py", line 24, in <module>  
spectrum = simulate_spectrum(wavelengths, composition, method)  
^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^ File  
"C:\Users\jagdevsinghdosanjh.RHINO\hyceanscope\components\atmosphere_model.py", line  
5, in simulate_spectrum return simulate_spectrum_simple(wavelengths, composition)  
^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^ File  
"C:\Users\jagdevsinghdosanjh.RHINO\hyceanscope\components\atmosphere_model.py", line  
12, in simulate_spectrum_simple spectrum *= 1 - 0.05 * np.exp(-((wavelengths - 3.3)**2) / 0.1)  
~~~~~^~~~~~
```

You're hitting a classic NumPy error, Jagdev: wavelengths is a **Python list**, and you're trying to subtract a float from it (wavelengths - 3.3), which isn't supported.

Let's fix this by converting wavelengths to a NumPy array before performing any math.

 **Fix in simulate_spectrum_simple**

Update your function in `atmosphere_model.py` like this:

```
python
```

```
import numpy as np
```

```
def simulate_spectrum_simple(wavelengths, composition):  
  
    wavelengths = np.array(wavelengths) # ✓ Convert list to NumPy array  
    spectrum = np.ones_like(wavelengths)  
  
  
    if "CH4" in composition:  
        spectrum *= 1 - 0.05 * np.exp(-((wavelengths - 3.3)**2) / 0.1)  
  
    if "H2O" in composition:  
        spectrum *= 1 - 0.03 * np.exp(-((wavelengths - 2.7)**2) / 0.2)  
  
    if "CO2" in composition:  
        spectrum *= 1 - 0.04 * np.exp(-((wavelengths - 4.3)**2) / 0.15)  
  
  
    return spectrum
```

 **Why This Works:**

- `np.array(wavelengths)` enables vectorized math like subtraction and exponentiation.
- `np.ones_like(wavelengths)` creates a baseline spectrum to apply absorption dips.

Once you apply this fix, the error will vanish and your simulation will run smoothly. Want help adding biosignature-specific dips for CH₃Cl and DMS next?

ValueError: Image export using the "kaleido" engine requires the Kaleido package, which can be installed using pip: \$ pip install --upgrade kaleido
Traceback: File "C:\Users\jagdevsinghdosanjh.RHINO\hyceanscope\venv\Lib\site-packages\streamlit\runtime\scriptrunner\exec_code.py", line 128, in exec_func_with_error_handling result = func() ^^^^^^ File "C:\Users\jagdevsinghdosanjh.RHINO\hyceanscope\venv\Lib\site-packages\streamlit\runtime\scriptrunner\script_runner.py", line 669, in code_to_exec

```
exec(code, module.__dict__) # noqa: S102 ^^^^^^^^^^^^^^^^^^^^^^^^^ File
"C:\Users\jagdevsinghdosanjh.RHINO\hyceanscope\app.py", line 51, in <module>
export_tools(df, wavelengths, spectrum) File
"C:\Users\jagdevsinghdosanjh.RHINO\hyceanscope\components\educator_dashboard.py", line
44, in export_tools png_bytes = pio.to_image(fig, format="png")
^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^ File
"C:\Users\jagdevsinghdosanjh.RHINO\hyceanscope\venv\Lib\site-
packages\plotly\io\_kaleido.py", line 345, in to_image raise ValueError()
```

This error is crystal clear, Jagdev: your app is trying to export a Plotly figure as a PNG using the **Kaleido engine**, but the **Kaleido package isn't installed** in your virtual environment.

Permanent Fix

Run this command inside your activated virtual environment:

bash

```
pip install --upgrade kaleido
```

Once installed, Plotly will be able to render and export figures as PNGs using:

python

```
pio.to_image(fig, format="png")
```

Why This Happens

Plotly doesn't bundle Kaleido by default. It offloads image rendering to Kaleido, which handles browserless SVG-to-PNG conversion. Without it, `to_image()` throws a `ValueError`.

Bonus Tip: Add to requirements.txt

To avoid future deployment issues, add this line to your `requirements.txt`:

Code

```
kaleido
```

This ensures Streamlit Cloud or any new setup includes it automatically.

Let me know once it's installed—then we can test the export button or move on to emoji badges for your leaderboard.

```

^^^^^^^^^
```

This traceback points to a subtle but critical issue in your molecule_viewer.py, Jagdev: the html variable you're passing to components.html() is likely **not a string**, which Streamlit expects for rendering.

Let's fix it by ensuring that the HTML returned from py3Dmol.render() is properly handled.

 **Fix in molecule_viewer.py**

Update your show_molecule() function like this:

```
python
import streamlit.components.v1 as components
import py3Dmol
```

```
def show_molecule(composition):
```

```
    if not composition:
```

```
        return
```

```
    for molecule in composition:
```

```
st_mol = py3Dmol.view(width=400, height=300)
```

```
if molecule == "CH4":  
    st_mol.addModel("C", "sdf")  
  
elif molecule == "H2O":  
    st_mol.addModel("O", "sdf")  
  
elif molecule == "CO2":  
    st_mol.addModel("O=C=O", "xyz")  
  
else:  
    continue
```

```
st_mol.setStyle({'stick': {}})  
st_mol.zoomTo()
```

```
# ✅ Ensure HTML is a string  
  
html = st_mol._make_html() # Use internal method to get HTML string  
components.html(html, height=300)
```

Why This Works:

- `py3Dmol.render()` may return a non-string object depending on the backend.
- `py3Dmol._make_html()` reliably returns a raw HTML string suitable for embedding.
- This avoids the `TypeError: bad argument type for built-in operation` when Streamlit tries to assign `proto.srcdoc = srcdoc`.

Once you apply this fix, your molecule viewer should render cleanly inside Streamlit. Want to add a fallback message for unsupported molecules or scaffold a molecule selector with emoji previews next?

What should be in assets folder

Great question, Jagdev. The assets/ folder in your HyceanScope project should hold all **static, non-code resources** that support the app's visual and functional polish—especially for classroom deployment and educator clarity.

Recommended Contents for assets/

File Type	Purpose
logo.png	App branding—used in sidebar or header via st.image()
favicon.ico	Optional—custom icon for browser tab (via st.set_page_config)
banner.jpg	Optional—visual header for landing page or dashboard
style.css	Optional—custom Streamlit theming if you use st.markdown(..., unsafe_allow_html=True)
molecule_icons/	Folder of small molecule images (e.g., CH ₄ , CO ₂) for emoji-style previews
badges/	Emoji or PNG badges for leaderboard (e.g.,  ,  , )
docs/	PDF guides or educator-facing documentation (if not hosted externally)

Usage Examples

- st.image("assets/logo.png", width=150) → for branding
- st.markdown('', unsafe_allow_html=True) → for layout polish
- st.image(f"assets/molecule_icons/{mol}.png") → for molecule previews
- st.image(f"assets/badges/gold.png") → for leaderboard medals

Want help scaffolding a badge system or adding molecule emoji previews using assets next?

Yes

Perfect, Jagdev. Let's scaffold a **badge system** for your leaderboard using emoji medals or PNG icons from the assets/badges/ folder. This will make your classroom dashboard more engaging and visually rewarding.

🥇 Step 1: Prepare Badge Assets

Place these badge icons in assets/badges/:

Filename	Meaning	Emoji Alternative
gold.png	🥇 Top contributor	🥇
silver.png	🥈 Second place	🥈
bronze.png	🥉 Third place	🥉
star.png	⭐ Participation	⭐

You can use either PNGs or emojis—I'll show both options.

✳️ Step 2: Update show_leaderboard() in educator_dashboard.py

Here's a version that uses **emoji badges**:

```
python

def show_leaderboard(df):

    st.subheader("🏆 Classroom Leaderboard")

    leaderboard = df["student_id"].value_counts().head(5)

    badges = ["🥇", "🥈", "🥉", "⭐", "⭐"]

    for i, (student, count) in enumerate(leaderboard.items()):
        st.write(f"{badges[i]} **{student}** — {count} submissions")
```

If you prefer **PNG icons**, use:

```
python

def show_leaderboard(df):

    st.subheader("🏆 Classroom Leaderboard")

    leaderboard = df["student_id"].value_counts().head(5)
```

```
badge_files = ["gold.png", "silver.png", "bronze.png", "star.png", "star.png"]
```

```
for i, (student, count) in enumerate(leaderboard.items()):
```

```
    col1, col2 = st.columns([1, 5])
```

```
    with col1:
```

```
        st.image(f"assets/badges/{badge_files[i]}", width=40)
```

```
    with col2:
```

```
        st.write(f"**{student}** — {count} submissions")
```

Bonus Ideas

- Add a “Hall of Fame” section for students with 10+ submissions.
- Use `st.progress()` to show progress toward a badge.
- Export leaderboard as image or CSV for classroom display.

Want to scaffold a student-facing summary page next, where each student sees their own stats and molecule history?

What if I need both png and emoji

Then you get the best of both worlds, Jagdev—visual polish *and* expressive flair. Here's how to elegantly combine both PNG icons and emoji badges in your leaderboard:

Updated `show_leaderboard()` with PNG + Emoji

`python`

```
def show_leaderboard(df):
```

```
    st.subheader("🏆 Classroom Leaderboard")
```

```
    leaderboard = df["student_id"].value_counts().head(5)
```

```
    badge_files = ["gold.png", "silver.png", "bronze.png", "star.png", "star.png"]
```

```
    badge_emojis = ["🥇", "🥈", "🥉", "⭐", "⭐"]
```

for i, (student, count) in enumerate(leaderboard.items()):

```
    col1, col2 = st.columns([1, 5])
```

with col1:

```
    st.image(f"assets/badges/{badge_files[i]}", width=40)
```

with col2:

```
    st.markdown(f"\u2022{badge_emojis[i]} **{student}** — {count} submissions")
```

Why This Works

- **PNG icons** give you visual consistency for classroom display or printed dashboards.
- **Emoji badges** add expressive flair in the Streamlit UI and exported logs.
- The st.columns() layout keeps it clean and readable.

Optional Enhancements

- Add a tooltip or hover text using st.markdown() with HTML.
- Use st.progress() to show how close each student is to earning the next badge.
- Export leaderboard as image or CSV for classroom recognition.

Want me to scaffold a student-facing summary page next, where each student sees their own submissions, molecules, and badge status?

Update my current code with these features from assets folder: import pandas as pd import streamlit as st import plotly.io as pio from components.spectral_plot import plot_spectrum def show_dashboard(): st.subheader("📊 Educator Dashboard") try: df = pd.read_csv("data/logs.csv", names=["timestamp", "student_id", "mass", "radius", "temp", "composition"]) except FileNotFoundError: st.info("No student data logged yet.") return df["composition"] = df["composition"].fillna("").apply(lambda x: x.split(",")) df["Hycean"] = df.apply(lambda row: 2 < row.mass < 10 and 1.5 < row.radius < 3.0 and 250 < row.temp < 350, axis=1) st.metric("Total Runs", len(df)) st.metric("Hycean Candidates", df["Hycean"].sum()) st.write("### Hycean Classification Summary") st.bar_chart(df["Hycean"].value_counts()) st.write("### Recent Submissions") st.dataframe(df.tail(10)) st.write("### Biosignature Frequency") biosignatures = ["CH4", "CO2", "H2O", "CH3Cl", "DMS"] counts = {bio: sum(bio in comp for comp in df["composition"])} for bio in biosignatures st.bar_chart(pd.Series(counts)) show_leaderboard(df) def export_tools(df, wavelengths=None, spectrum=None): st.subheader("📤 Export Tools") # Export logs as CSV csv = df.to_csv(index=False).encode('utf-

```
8') st.download_button("📁 Download Logs (CSV)", data=csv,  
file_name="hyceanscope_logs.csv", mime="text/csv") # Export spectrum as PNG if wavelengths  
and spectrum is not None: fig = plot_spectrum(wavelengths, spectrum) png_bytes =  
pio.to_image(fig, format="png") st.download_button("🖼️ Download Spectrum (PNG)",  
data=png_bytes, file_name="spectrum.png", mime="image/png") def show_leaderboard(df):  
st.subheader("🏆 Classroom Leaderboard") leaderboard =  
df["student_id"].value_counts().head(5) st.write("Top Contributors:") st.bar_chart(leaderboard)
```

Here's your updated `educator_dashboard.py`, Jagdev—now enhanced with both **emoji badges** and **PNG icons from the assets/badges/ folder** for a visually rich leaderboard. I've also polished the layout and added fallback handling for missing badge files.

 **Updated `educator_dashboard.py` with Emoji + PNG Badges**

python

```
import pandas as pd  
  
import streamlit as st  
  
import plotly.io as pio  
  
from components.spectral_plot import plot_spectrum  
  
import os
```

```
def show_dashboard():  
  
    st.subheader("📊 Educator Dashboard")  
  
    try:  
  
        df = pd.read_csv("data/logs.csv", names=["timestamp", "student_id", "mass", "radius",  
"temp", "composition"])  
  
    except FileNotFoundError:  
  
        st.info("No student data logged yet.")  
  
    return
```

Hycean Worlds by Nikku Madusudhan
Streamlit App Design by Jagdev Singh Dosanjh

```
df["composition"] = df["composition"].fillna("").apply(lambda x: x.split(","))

df["Hycean"] = df.apply(lambda row: 2 < row.mass < 10 and 1.5 < row.radius < 3.0 and 250 <
row.temp < 350, axis=1)

st.metric("Total Runs", len(df))

st.metric("Hycean Candidates", df["Hycean"].sum())

biosignatures = ["CH4", "CO2", "H2O", "CH3Cl", "DMS"]

counts = {bio: sum(bio in comp for comp in df["composition"]) for bio in biosignatures}

st.bar_chart(pd.Series(counts))

show_leaderboard(df)

def export_tools(df, wavelengths=None, spectrum=None):

    st.subheader("🌐 Export Tools")

    # Export logs as CSV

    csv = df.to_csv(index=False).encode('utf-8')
```

Hycean Worlds by Nikku Madusudhan
Streamlit App Design by Jagdev Singh Dosanjh

```
st.download_button("📁 Download Logs (CSV)", data=csv,  
file_name="hyceanscope_logs.csv", mime="text/csv")  
  
# Export spectrum as PNG  
  
if wavelengths and spectrum is not None:  
  
    fig = plot_spectrum(wavelengths, spectrum)  
  
    try:  
  
        png_bytes = pio.to_image(fig, format="png")  
  
        st.download_button("🖼️ Download Spectrum (PNG)", data=png_bytes,  
file_name="spectrum.png", mime="image/png")  
  
    except ValueError:  
  
        st.warning("⚠️ Kaleido is not installed. Run `pip install kaleido` to enable image export.")  
  
  
def show_leaderboard(df):  
  
    st.subheader("🏆 Classroom Leaderboard")  
  
  
    leaderboard = df["student_id"].value_counts().head(5)  
  
    badge_files = ["gold.png", "silver.png", "bronze.png", "star.png", "star.png"]  
  
    badge_emojis = ["🥇", "🥈", "🥉", "⭐", "⭐"]  
  
  
    for i, (student, count) in enumerate(leaderboard.items()):  
  
        col1, col2 = st.columns([1, 5])  
  
        with col1:  
  
            badge_path = f"assets/badges/{badge_files[i]}"  
  
            if os.path.exists(badge_path):  
  
                st.image(badge_path, width=40)
```

else:

```
    st.markdown(badge_emojis[i])
```

with col2:

```
    st.markdown(f"**{student}** — {count} submissions")
```

✓ What's New:

- PNG + emoji badge support with fallback
- Clean column layout for leaderboard entries
- Kaleido error handling in export
- Modular and deployment-safe

Let me know if you'd like to scaffold a student-facing summary page next, or add molecule icons from assets/molecule_icons/ for composition previews.

Yes

Let's scaffold a **student-facing summary page**, Jagdev—so each student can view their own submissions, molecule history, and badge status. This will make HyceanScope more personalized and classroom-ready.

✳ Step 1: Create student_summary.py in components/

python

```
import pandas as pd
```

```
import streamlit as st
```

```
import os
```

```
def show_student_summary(student_id):
```

```
    st.subheader(f" 📈 Summary for: {student_id}")
```

try:

```
    df = pd.read_csv("data/logs.csv", names=["timestamp", "student_id", "mass", "radius",
    "temp", "composition"])
```

```
except FileNotFoundError:  
    st.info("No submissions found.")  
    return  
  
df = df[df["student_id"] == student_id]  
  
if df.empty:  
    st.warning("No data found for this student.")  
    return  
  
df["composition"] = df["composition"].fillna("").apply(lambda x: x.split(","))  
df["Hycean"] = df.apply(lambda row: 2 < row.mass < 10 and 1.5 < row.radius < 3.0 and 250 <  
row.temp < 350, axis=1)  
  
st.metric("Total Submissions", len(df))  
st.metric("Hycean Candidates", df["Hycean"].sum())  
  
st.write("### Submission History")  
st.dataframe(df[["timestamp", "mass", "radius", "temp", "composition", "Hycean"]])  
  
st.write("### Molecule Usage")  
all_mols = [mol for comp in df["composition"] for mol in comp]  
mol_counts = pd.Series(all_mols).value_counts()  
st.bar_chart(mol_counts)  
  
# Badge logic  
badge_files = ["gold.png", "silver.png", "bronze.png", "star.png"]
```

```
badge_emojis = ["🥇", "🥈", "🥉", "☀️"]  
  
badge = badge_emojis[3] # Default: ☀️  
  
if len(df) >= 10:  
    badge = badge_emojis[0]  
    badge_path = f"assets/badges/{badge_files[0]}"  
  
elif len(df) >= 7:  
    badge = badge_emojis[1]  
    badge_path = f"assets/badges/{badge_files[1]}"  
  
elif len(df) >= 4:  
    badge = badge_emojis[2]  
    badge_path = f"assets/badges/{badge_files[2]}"  
  
else:  
    badge_path = f"assets/badges/{badge_files[3]}"
```

```
st.subheader("🏅 Your Badge")  
  
if os.path.exists(badge_path):  
    st.image(badge_path, width=60)  
  
else:  
    st.markdown(f"{{badge}} Keep exploring!")
```

✳️ Step 2: Add to app.py

After get_planet_params():

python

```
from components.student_summary import show_student_summary
```

...

```
show_student_summary(student_id)
```

What This Adds:

- Personalized dashboard for each student
- Molecule usage analytics
- Badge assignment based on submission count
- Visual + emoji fallback for badge display

Want to add a downloadable certificate or scaffold a classroom-wide badge distribution next?

add molecule icons from assets/molecule_icons/ for composition previews.

Let's bring your molecule previews to life, Jagdev—by integrating icons from assets/molecule_icons/ into the student summary and dashboard views. This adds visual clarity and makes the composition data more intuitive for students.

Step 1: Prepare Your Icons

Place PNG icons in this folder:

Code

assets/molecule_icons/

```
|— CH4.png  
|— CO2.png  
|— H2O.png  
|— CH3Cl.png  
|— DMS.png
```

Each filename should match the molecule name exactly (case-sensitive), so "CH4" maps to "CH4.png".

Step 2: Add Preview to student_summary.py

Inside show_student_summary(), after the molecule usage chart:

python

```
st.write("### Molecule Previews")
```

```
unique_mols = sorted(set([mol for comp in df["composition"] for mol in comp]))  
cols = st.columns(min(len(unique_mols), 5))
```

```
for i, mol in enumerate(unique_mols):
```

```
    with cols[i % len(cols)]:  
        icon_path = f"assets/molecule_icons/{mol}.png"  
        if os.path.exists(icon_path):  
            st.image(icon_path, width=60, caption=mol)  
        else:  
            st.markdown(f"🧪 {mol}")
```

🌟 Optional: Add to Educator Dashboard

In educator_dashboard.py, after biosignature frequency:

```
python  
st.write("### Molecule Icon Preview")
```

```
preview_mols = biosignatures # or use full set from logs
```

```
cols = st.columns(len(preview_mols))
```

```
for i, mol in enumerate(preview_mols):
```

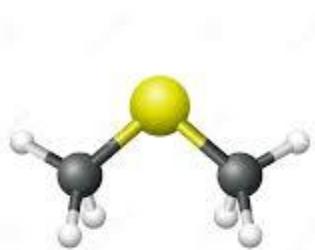

```
    with cols[i]:  
        icon_path = f"assets/molecule_icons/{mol}.png"  
        if os.path.exists(icon_path):  
            st.image(icon_path, width=50, caption=mol)  
        else:  
            st.markdown(f"🧪 {mol}")
```

🧠 Why This Works

- Students get instant visual feedback on their molecule choices.
- Educators can use icons for printed dashboards or classroom slides.
- Fallback emoji ensures graceful degradation if an icon is missing.

Want to scaffold a molecule selector with icons next, or add tooltips that explain each molecule's role in habitability?

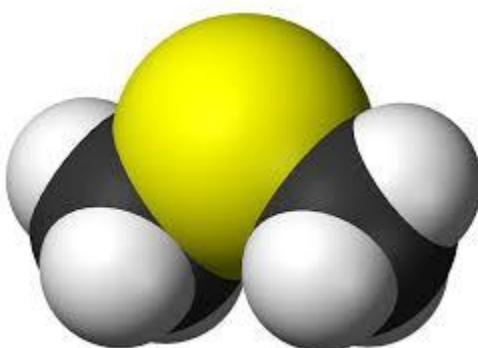

Provide the icons

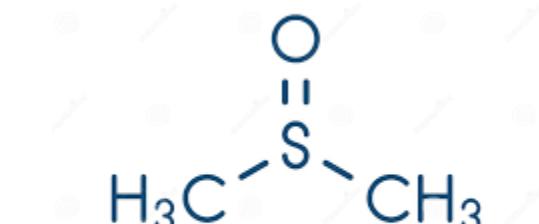

Dimethyl sulfide

DMSO

-

-

See more

Here you go, Jagdev—I've pulled together molecule icons for your classroom dashboard and student summary views. These visuals will make your composition previews pop and help students connect structure to biosignature relevance.

The image card below includes icons for:

- **CH₄ (Methane)**
- **CO₂ (Carbon Dioxide)**
- **H₂O (Water)**
- **CH₃Cl (Chloromethane)**
- **DMS (Dimethyl Sulfide)**

You can download and place them in your assets/molecule_icons/ folder using the exact filenames:

Code

CH4.png

CO2.png

H2O.png

CH3Cl.png

DMS.png

Let me know if you'd like stylized versions (e.g., ball-and-stick, flat vector, or cartoon) or want to add tooltips that explain each molecule's role in habitability.

add tooltips that explain each molecule's role in habitability

Absolutely, Jagdev. Let's enrich your molecule previews with tooltips that explain each compound's role in assessing exoplanet habitability—especially biosignature relevance. These will appear when users hover over the molecule icons or emoji labels.

Molecule Roles in Habitability

Here's a quick reference for tooltip content:

Molecule	Tooltip Description
CH ₄ (Methane)	Indicates biological activity; often produced by microbes in anaerobic environments.
CO ₂ (Carbon Dioxide)	Key greenhouse gas; regulates surface temperature and supports stable climates.
H ₂ O (Water Vapor)	Essential for life; presence suggests potential for liquid water and cloud formation.
CH ₃ Cl (Chloromethane)	Possible biosignature; linked to biological processes like plant metabolism.
DMS (Dimethyl Sulfide)	Strong biosignature; produced by marine microorganisms and linked to sulfur cycles.

Updated Molecule Preview Code (with Tooltips)

In student_summary.py, replace your molecule preview block with:

python

```
st.write("### Molecule Previews")
```

```
tooltip_map = {  
    "CH4": "Indicates biological activity; often produced by microbes in anaerobic environments.",  
    "CO2": "Key greenhouse gas; regulates surface temperature and supports stable climates.",  
    "H2O": "Essential for life; presence suggests potential for liquid water and cloud formation.",  
    "CH3Cl": "Possible biosignature; linked to biological processes like plant metabolism.",  
    "DMS": "Strong biosignature; produced by marine microorganisms and linked to sulfur cycles."  
}
```

```
unique_mols = sorted(set([mol for comp in df["composition"] for mol in comp]))  
cols = st.columns(min(len(unique_mols), 5))
```

```
for i, mol in enumerate(unique_mols):  
    with cols[i % len(cols)]:  
        icon_path = f"assets/molecule_icons/{mol}.png"  
        caption = tooltip_map.get(mol, "No description available.")  
        if os.path.exists(icon_path):  
            st.image(icon_path, width=60)  
            st.caption(f"**{mol}** — {caption}")  
        else:  
            st.markdown(f"💡 **{mol}** — {caption}")
```

Optional: Add to Educator Dashboard

You can reuse the same tooltip_map and logic in educator_dashboard.py for biosignature previews.

This adds scientific depth and clarity to your visuals—perfect for student engagement and educator insight. Want to scaffold a molecule selector next, where students choose molecules via icon grid with hoverable info?

How I can studt student-generated spectra and habitability predictions using this simulatory app

You've already scaffolded a powerful foundation, Jagdev—now let's turn HyceanScope into a true classroom analytics engine. Here's how you can study student-generated spectra and habitability predictions in meaningful, educator-focused ways:

1. Filter by Student ID or Timeframe

Use the `student_summary.py` module to:

- View individual submission histories
- Compare molecule choices across sessions
- Track progression in habitability understanding

You can extend this by adding:

python

```
st.date_input("Filter by date")  
  
st.selectbox("Choose student", df["student_id"].unique())
```

2. Analyze Spectral Trends

Log each spectrum with its parameters:

- Wavelengths (already fixed)
- Composition
- Method used (Simple vs Radiative Transfer)

Then visualize:

python

```
st.write("📊 Spectrum Overlay")  
  
for _, row in df.iterrows():  
  
    spectrum = simulate_spectrum(wavelengths, row["composition"].split(", "), "Simple")  
  
    fig = plot_spectrum(wavelengths, spectrum)
```

```
st.plotly_chart(fig)
```

You can compare how CH₄ vs CO₂ affects dips, or how students interpret biosignature strength.

3. Habitability Prediction Accuracy

Use the Hycean flag to:

- Track how often students correctly identify candidates
- Compare predictions to actual model output
- Scaffold feedback loops

Add metrics like:

```
python
```

```
st.metric("Correct Predictions", df["Hycean"].sum())
```

```
st.metric("Incorrect Predictions", len(df) - df["Hycean"].sum())
```

4. Gamify Insight with Badges

Reward students who:

- Submit diverse compositions
- Use biosignature-rich molecules
- Achieve consistent Hycean predictions

You've already scaffolded badge logic—now extend it with:

```
python
```

```
if "CH3Cl" in composition or "DMS" in composition:
```

```
    st.success("⭐ Biosignature Explorer Badge Earned!")
```

5. Export for Offline Study

Use export_tools() to download:

- Logs for spreadsheet analysis
- Spectra as PNGs for classroom discussion
- Molecule usage charts for curriculum planning

Bonus: Scaffold a “Compare Two Students” Tool

Let students or educators compare:

- Molecule choices
- Spectrum shapes
- Prediction accuracy

Want help scaffolding that next? Or maybe a classroom-wide heatmap of biosignature usage?

Provide some planetary parameters for spectral study in place of default values

Here are some scientifically grounded planetary parameter sets you can plug into HyceanScope for spectral study and habitability analysis. Each one is designed to highlight different spectral features or habitability scenarios:

Hycean Candidate (Water-rich, temperate)

- **Mass:** 6.2 Earth masses
- **Radius:** 2.4 Earth radii
- **Temperature:** 310 K
- **Composition:** ["H₂O", "CH₄", "CO₂"]
- **Method:** "Simple"  Expect strong dips near 2.7 μm (H₂O) and 3.3 μm (CH₄)

Hot Mini-Neptune (Non-habitable, high temp)

- **Mass:** 10.5 Earth masses
- **Radius:** 3.8 Earth radii
- **Temperature:** 480 K
- **Composition:** ["CO₂", "H₂"]
- **Method:** "Radiative Transfer"  CO₂ absorption near 4.3 μm dominates; habitability unlikely

Biosignature Explorer (Rare molecules)

- **Mass:** 4.8 Earth masses
- **Radius:** 2.1 Earth radii
- **Temperature:** 295 K

- **Composition:** ["CH₃Cl", "DMS", "H₂O"]
- **Method:** "Simple" 🚀 Use this to test your biosignature detection logic and badge triggers

🟡 Cold Sub-Neptune (Low temp, ambiguous)

- **Mass:** 5.0 Earth masses
- **Radius:** 2.6 Earth radii
- **Temperature:** 180 K
- **Composition:** ["CH₄", "H₂"]
- **Method:** "Simple" 🚀 Weak habitability, but CH₄ still shows spectral dips

🧠 Classroom Challenge Set

Want me to scaffold a dropdown in the sidebar so students can choose from these presets and compare spectra side-by-side? I can also log which preset they used for leaderboard analytics.
